Welcome to the Rational University course on Requirements Management with Use Cases. This course teaches you how to improve your requirements management process in a team environment. We discuss many ways of managing and specifying requirements, with special focus on how to build a Use-Case Model of requirements. The course describes how the development process is driven by the requirements in the Use-Case Model.

IBM

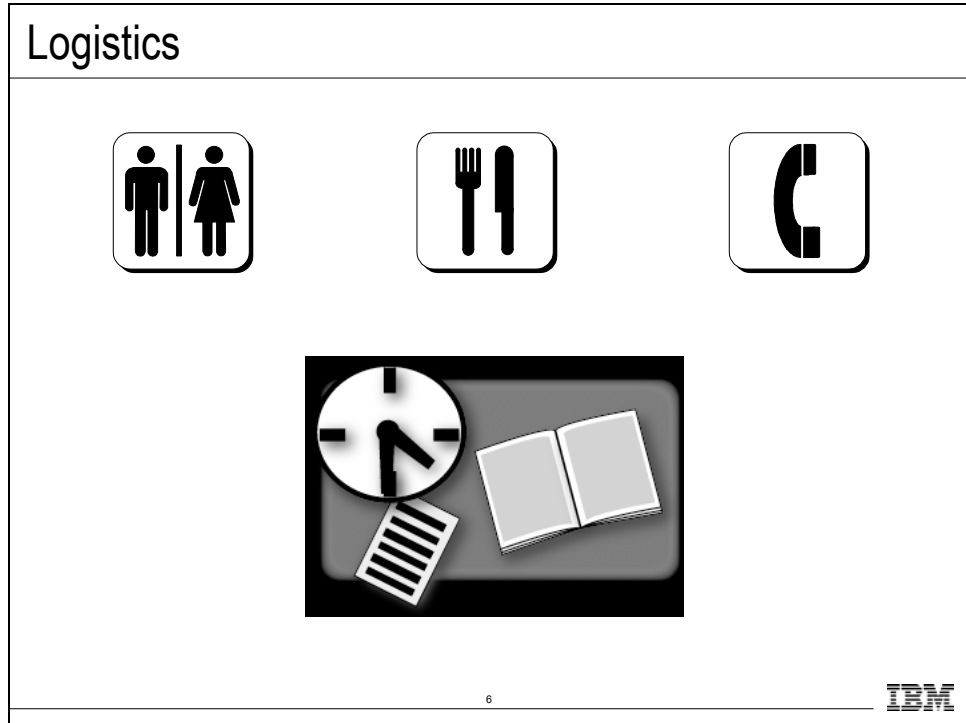

The pyramid represents a roadmap for the course.

Managing requirements involves the translation of stakeholder requests into a set of needs and system features. These in turn are detailed into specifications for functional and nonfunctional requirements. Detailed specifications are translated into test procedures, design, implementation, and user documentation.

Traceability allows us to:

- Assess the project impact of a change in a requirement.
- Assess the impact of a failure of a test on requirements (that is, if the test fails, the requirement may not be satisfied.)
- Manage the scope of the project.
- Verify that all requirements of the system are fulfilled by the implementation.
- Verify that the application does only what it was intended to do.
- Manage change.
